

Bond Polarity and Electronegativity

- **Electronegativity (EN):** intrinsic ability of an atom to attract the shared electrons in a covalent bond
- Differences in EN produce bond polarity
- Arbitrary scale.
- F is most electronegative (EN = 4.0), Cs is least (EN = 0.7)
- Metals on left side of periodic table attract electrons weakly, lower EN
- Halogens and other reactive nonmetals on right side of periodic table attract electrons strongly, higher electronegativities
- □ EN of C = 2.5

Bond Polarity and Inductive **Effect**

- Nonpolar Covalent Bonds: atoms with similar EN difference < 0.5
- Polar Covalent Bonds: Difference in EN of atoms < 1.7</p>
- Ionic Bonds: Difference in EN > 1.7
 - C-H bonds, relatively nonpolar
 - □ C-O, C-X bonds (more electronegative elements) are polar
- Bonding electrons toward electronegative atom
 - \blacksquare C acquires partial positive charge, δ +
 - □ Electronegative atom acquires partial negative charge,

Electrostatic Potential Maps Electrostatic potential maps show calculated charge distributions Colors indicate electron-rich (red) and electron-poor (blue) regions Arrows indicate direction of bond polarity

Predicting the Polarity Bonds

- $\hfill\Box$ Predict the polarization of the O-H bonds in water.
- □ Strategy Look at the electronegativity table to see which atoms attract the electrons more strongly.
- □ Oxygen (EN = 3.5) is more electronegative than Hydrogen (EN = 2.1) and it therefore attracts electrons more strongly. The difference is 1.4 is O-H bond is strongly polarized.
